Section 5

Overview

- 1. Transition Dynamics
 - Permanent shock
- 2. Andreas's Repository
 - Adaptive Sparse Grid
 - Partial Equilibrium
 - General Equilibrium

Section 5-1: Transition Dynamics

Transition Dynamics

- We have solved for the long-run stationary equilibrium of the Huggett economy under fixed parameters.
- Now, consider a permanent increase in unemployment risk, represented by λ_e .
- Our goal is to analyze the transition dynamics resulting from this parameter change.

Dynamics of Wealth Distribution

Time Path of Equilibrium Interest Rate

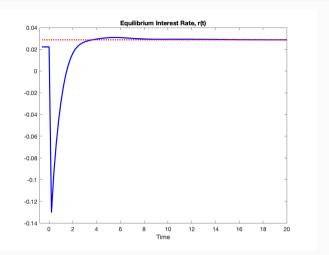

Figure 3: Time Path of Equilibrium Interest Rate

System of Equations

The system to be solved is:

$$\rho V_{j}(a,t) = \max_{c} u(c) + \partial_{a} V_{j}(a,t) \left[z_{j} + r(t)a - c \right] + \lambda_{j} \left[V_{-j}(a,t) - V_{j}(a,t) \right] + \frac{\partial_{t} V_{j}(a,t)}{\partial_{t} V_{j}(a,t)}$$
(1)

$$c_j(a,t) = (u')^{-1} (\partial_a V_j(a,t))$$
 (2)

$$s_j(a,t) = z_j + r(t)a - c_j(a,t)$$
 (3)

System of Equations

The system to be solved is:

$$\rho V_j(a,t) = \max_{a} u(a) + \partial_a V_j(a,t) [z_j + r(t)a - c] + \lambda_j [V_{-j}(a,t) - V_j(a,t)] + \partial_t V_j(a,t)$$
(1)

$$c_j(a,t) = (u')^{-1} \left(\partial_a V_j(a,t) \right) \tag{2}$$

$$s_j(a,t) = z_j + r(t)a - c_j(a,t)$$
 (3)

$$\partial_t g_j(a,t) = -\partial_a \left[s_j(a,t) g_j(a,t) \right] - \lambda_j g_j(a,t) + \lambda_{-j} g_{-j}(a,t) \tag{4}$$

System of Equations

The system to be solved is:

$$\rho V_j(a,t) = \max_c u(c) + \partial_a V_j(a,t) [z_j + r(t)a - c] + \lambda_j [V_{-j}(a,t) - V_j(a,t)] + \partial_t V_j(a,t)$$
(1)

$$c_j(a,t) = (u')^{-1} \left(\partial_a V_j(a,t) \right) \tag{2}$$

$$s_j(a,t) = z_j + r(t)a - c_j(a,t)$$
(3)

$$\partial_t g_j(a,t) = -\partial_a \left[s_j(a,t) g_j(a,t) \right] - \lambda_j g_j(a,t) + \lambda_{-j} g_{-j}(a,t) \tag{4}$$

$$0 = \frac{dS(r(t))}{dt} = \int_a^\infty s_e(a, t)g_e(a, t) da + \int_a^\infty s_u(a, t)g_u(a, t) da$$
 (5)

Econ 202A Macroeconomics: Section 5

Algorithm

- 1. Solve for the long-run equilibrium for both the initial and terminal states:
 - Set the initial condition $g_i^n(a,0)$ for all iterations n as $g_i(a)$ from the initial equilibrium.
 - Set the terminal condition $V_i^n(a, T)$ for all iterations n as $V_j(a)$ from the terminal equilibrium.
- 2. Make an initial guess for the function $r^0(t)$. A good initial value is $r^0(t) = r_T$ for all t, based on the terminal equilibrium.

For iterations n = 0, 1, 2, ...

- 3. Given $r^n(t)$, solve the HJB equation backward in time with the terminal condition $V_j^n(a,T)=V_j(a)$. This yields the time path of $V_j^n(a,t)$ and the implied saving policy function $s_i^n(a,t)$. Ensure that the transition matrix \mathbf{P}^n is computed and stored for each iteration.
- 4. Using $s_j^n(a,t)$, solve the Kolmogorov-Forward (KF) equation forward in time with the initial condition $g_i^n(a,0)$ to compute the time path of $g_i^n(a,t)$.

Econ 202A Macroeconomics: Section 5

Algorithm

5. Calculate the asset supply for all t:

$$S^n(t) = \int_{\underline{a}}^{\infty} a g_e^n(a, t) da + \int_{\underline{a}}^{\infty} a g_u^n(a, t) da$$

6. Update the guess for r(t) using:

$$r^{n+1}(t) = r^n(t) - \xi \frac{dS^n(t)}{dt}$$

where $\xi > 0$ is a step size.

7. Stop the iteration when $r^{n+1}(t)$ is sufficiently close to $r^n(t)$.

Approximate the value function at I discrete points in the wealth dimension and I_t discrete points in the time dimension, and use the shorthand notation $v_{i,j}^{it} = v_j(a_i, t_{it})$ where $i = 1, \dots, I$ and $it = 0, 1, \dots, I_t$ with a uniform time step size $\Delta t = t(it+1) - t(it)$. The discrete approximation to the time-dependent HJB (1) is:

$$\rho V_{i,j}^{it} = U(c_{i,j}^{it+1}) + (V_{i,j}^{it})' \left[z_j + r^{it+1} a_i - c_{i,j}^{it+1} \right] + \lambda_j \left[V_{i,-j}^{it} - V_{i,j}^{it} \right] + \frac{V_{i,j}^{it+1} - V_{i,j}^{it}}{\Delta t}$$
(7)

with terminal condition $V_{i,j}^{I_t} = V_j(a_i)$.

Given V^{it+1} , this system can be written in matrix notation as:

$$\rho \mathbf{V}^{it} = U(\mathbf{c}^{it+1}) + \mathbf{P}^{it+1}\mathbf{V}^{it} + \frac{1}{\Delta t}(\mathbf{V}^{it+1} - \mathbf{V}^{it})$$
(8)

where $\mathbf{P^{it+1}}$ still has the interpretation of the transition matrix of the discretized stochastic process for (a_t, z_t) .

Given V^{it+1} , this system can be written in matrix notation as:

$$\rho \mathbf{V}^{it} = U(\mathbf{c}^{it+1}) + \mathbf{P}^{it+1}\mathbf{V}^{it} + \frac{1}{\Delta t}(\mathbf{V}^{it+1} - \mathbf{V}^{it})$$
(8)

where $\mathbf{P^{it+1}}$ still has the interpretation of the transition matrix of the discretized stochastic process for (a_t, z_t) .

Now each it has the interpretation of a time step instead of an iteration on the stationary value function. The reason for this similarity in the algorithm is that intuitively a stationary value function can be found by solving a time-dependent problem and going far enough back in time, i.e., as $t \to -\infty$.

Equivalently, solve the linear system:

$$\mathbf{V}^{\mathsf{it}} = \left((\rho + \frac{1}{\Delta t})\mathbf{I} - \mathbf{P}^{\mathsf{it}+1} \right)^{-1} \left[U(\mathbf{c}^{\mathsf{it}+1}) + \frac{1}{\Delta t} \mathbf{V}^{\mathsf{it}+1} \right]$$
(9)

(Step 4) Solving the Time-Dependent Kolmogorov Forward Equation

We approximate the density at I discrete points in the wealth dimension and I_t discrete points in the time dimension, and use the shorthand notation $g_{i,j}^{it} = g_j(a_i, t_{it})$. Given an initial condition $g_{i,j}^0 = g_j(a_i)$, the Kolmogorov Forward equation (4) is then easily solved.

One here has the option of using either an explicit method:

$$\frac{\mathbf{g}^{\mathsf{i}\mathsf{t}+1} - \mathbf{g}^{\mathsf{i}\mathsf{t}}}{\Delta t} = (\mathsf{P}^{\mathsf{i}\mathsf{t}})^\mathsf{T} \mathbf{g}^{\mathsf{i}\mathsf{t}} \quad \Longrightarrow \quad \mathbf{g}^{\mathsf{i}\mathsf{t}+1} = \Delta t (\mathsf{P}^{\mathsf{i}\mathsf{t}})^\mathsf{T} \mathbf{g}^{\mathsf{i}\mathsf{t}} + \mathbf{g}^{\mathsf{i}\mathsf{t}}$$

or an implicit method:

$$\frac{\mathbf{g}^{i\mathbf{t}+1} - \mathbf{g}^{i\mathbf{t}}}{\Delta t} = (\mathbf{P}^{i\mathbf{t}})^{\mathsf{T}} \mathbf{g}^{i\mathbf{t}+1} \quad \Longrightarrow \quad \mathbf{g}^{i\mathbf{t}+1} = (\mathbf{I} - \Delta t (\mathbf{P}^{i\mathbf{t}})^{\mathsf{T}})^{-1} \mathbf{g}^{i\mathbf{t}}$$
(10)

Both schemes preserve mass, but the implicit scheme is also guaranteed to preserve the positivity of g for arbitrary time steps Δt .

Repository

Andreas's Repository

- Repository link: https://github.com/schaab-lab/SparseEcon
- Explore this repository to extend the code you've written so far!
- Clone the repository and add the local path to your MATLAB code.

- This repository provides a toolbox for solving dynamic programming problems in continuous time using **adaptive sparse grids**. The method applies to a wide range of dynamic programming applications across various fields in economics (Schaab and Zhang, 2022).
- If you're interested, read Schaab and Zhang (2022).
- More resources: https://github.com/schaab-teaching/NumericalMethods

- Uniform grids:
 - Points are placed equidistantly across the domain.
 - Suffer from the "curse of dimensionality," where the number of grid points grows exponentially with added dimensions.

- Uniform grids:
 - Points are placed equidistantly across the domain.
 - Suffer from the "curse of dimensionality," where the number of grid points grows exponentially with added dimensions.
- Adaptive sparse grids:
 - Strategically remove points that contribute minimally to function approximation.
 - Use information like residual approximation error to dynamically refine the grid based on problem-specific needs.
